## ABSTRACT

Addition-Composition Fully Homomorphic Encryption is given in this paper to solve data security equation in cloud computation. An earlier attempt to solve security problem has been proposed by Craig Gentry, who combined additive and multiplicative operations, using lattice-based cryptography. Its construction started as a somewhat homomorphic encryption scheme that evaluates low-degree polynomials over encrypted data. He then modified it to make it bootstrappable and showed that any bootstrappable fully homomorphic encryption scheme can be converted into a fully homomorphic encryption. Subsequent efforts to improve on Craig's work still favor his approach, i.e. bootstrapping homomorphic cryptosystems with noisy ciphertexts into fully homomorphic cryptosystems. The approach in the design of the scheme in this paper is based on combining additive and composition properties making it complex to compromise. Finally, the scheme enables secure computation of cloud data without exposing it to deliberate risk.

## 1. Introduction

According to TechSoup Global Network (2012) survey results on cloud computing, over $90 \%$ were using cloud computing while $79 \%$ of the remaining intended to migrate to cloud services. Ateyaro \& Feyisetan (2011), Rachana \& Guruprasad (2014) and Gnanavelu \& Gunasekaran (2014) in their respective researches showed that data security is one major security concern for cloud computing. In analyzing cloud security issues, it has been concluded that the success of its adoption depends on the
benefits to risk and threat ratio. Researchers have focused on access controls as a measure to boost cloud computing adoptability by consumers. They proposed use of digital ID's for consumers to minimize unauthorized access and address non-repudiation issues in cloud computing services. In addressing unauthorized access and tampering, Sasidharan et al., (2011) proposed data-centric encryption security approach. Tiwari \& Mishra (2012) in their research recommended that developers should develop applications that provide encrypted data for security in cloud computing. Gonzalez et al., (2012) in their work carried a quantitative analysis of current security concerns in cloud computing and found out that there is still need to address those related to secure virtualization. Naruchitparames \& Gunes (2013) addressed security of data on transit through blind processing whereas Gupta et al., (2011) used block cipher method to propose hyper modern cryptography algorithm for confidentiality and integrity of data through data encryption but noted that encryption methods are easy to break especially when a key is used several times in encryption. Kaur (2012), Tebaa et al., (2013) and Gomathisankaran (2012) proposed the use of Fully Homomorphic Encryption scheme as an effective solution to cloud computing security. In all these research attempts, cryptography is appreciated as better solutions to cloud architecture security challenges. Ravindran \& Kaplana (2011) analyzed and recommended improvement on Fully Homomorphic Encryption for applications on cloud computing. However, the application of Fully Homomorphic Encryption experiences implementation defect due to its computational strain onto network and storage resources.

## 2. Preliminaries

In order to understand the derivation in this paper, we need the following fundamental concepts.
Definition 2. 1 If $\left(\mathrm{G},,^{*}\right)$ and $(\mathrm{H}, \circ)$ are groups, then a function $\mathrm{f}: \mathrm{G} \rightarrow \mathrm{H}$ is a homomorphism if

$$
\mathrm{f}(\mathrm{x}, \mathrm{y})=\mathrm{f}(\mathrm{x}) \mathrm{f}(\mathrm{y}) \quad \forall x, y \in G
$$

Definition 2.2 Cloud computing is a model for enabling ubiquitous, convenient, on-demand network access to a shared pool of configurable computing resources that can be rapidly provisioned and released with minimal management effort or service provider interaction.

Remark 2.3 This study describes a new technique of addition-Composition Homomorphic Encryption which has never been done in literature. There are Three Address Codes which are description of a series of strings for example $\alpha_{1}=a o p b$ where $\alpha 1, a, b$ names of parameters are while $o p$ is a random operator. Normally we have two operations.

We can express them as follows:

$$
\begin{aligned}
& \delta_{1}=\mathrm{a} \bullet \mathrm{~b} \\
& \delta_{2}=\mathrm{a}+\delta_{1}
\end{aligned}
$$

Where $\delta_{1}$ and $\delta_{2}$ are temporary variables formed by the compiler.

## Definition 2.4 (Mixed-Multiplicative Homomorphic Encryption)

We consider a large number $n$ such that $\mathrm{n}=l \bullet \mathrm{k}$ where $l$ and $k$ are large prime numbers. We adopt the following notations:
$Z_{l}=\{a: a \leq 1\} \quad$ the set of original plain text messages
$Z_{n}=\{a: a<n\}$ the set of cipher text message
$Q_{1}=\left\{b: b\right.$ is not an element of $\left.Z_{l}\right\} \quad$ set of encryption dues
Here the simple encryption is as follows (Updhaye \& Khot, 2013);
If y is encrypted as $\mathrm{y}=\mathrm{E}_{\mathrm{l}}(\mathrm{a}) \equiv \mathrm{b} \bmod \mathrm{n}$ then we can achieve it by picking a random number r and creating $\mathrm{b}=\mathrm{a}+\mathrm{rl}$. So if the encryption y is a number of $\mathrm{Z}_{\mathrm{n}}$ then we use the key $l$ to recover a $\mathrm{D}_{\mathrm{p}}(\mathrm{y}) \equiv \mathrm{y}$ $\bmod 1$.

Example 2.5 Let $\mathrm{l}=17, \mathrm{k}=13, \mathrm{n}=221=1 \bullet \mathrm{k}$ and $\mathrm{a}_{1}=8$ and $\mathrm{E}(8)=59, \mathrm{a}_{2}=2$ where $\mathrm{E}(2)=36$. Now (59x36) $\bmod 221=135$. Decrypting 135 yields $\mathrm{l}=135 \bmod 17$. This is similar to $\mathrm{a}_{1} \bullet \mathrm{a}_{2}=2 \bullet 8=16$.

Definition 2.6 Let V be a vector space a non-negative real-valued function $\|\|: \mathrm{V} \rightarrow \mathfrak{R}$ is called a norm if the following conditions are satisfied:
(1) $\quad\|x\| \geq 0$ and $\|x\|=0$ if and only if $\mathrm{x}=0 \quad \forall \mathrm{x} \in \mathrm{V}$
(2) $\quad\|x\|=|\lambda|\|x\| \forall x \in \mathrm{~V}$ and $\lambda \in \mathrm{K}$
(3) $\quad\|x+y\| \leq\|x\|+\|y\| \forall \mathrm{x}, \mathrm{y} \in \mathrm{V}$

Remark: 2.7 We treated the members of V in a probabilistic sense that is without loss of generality.
Definition 2.8 A family H of hash functions h: $\mathrm{X} \rightarrow \mathrm{Y}$ is $\varepsilon$-pairwise independent if

$$
\sum_{x \neq x^{\prime}}\left(\operatorname{Pr}_{h \leftarrow H}\left[h(x)=h\left(x^{\prime}\right)-\frac{1}{|Y|}\right) \leq\left|X^{2}\right| \bullet \frac{\varepsilon}{|Y|}\right.
$$

Remark 2.9 A necessary and sufficient condition here is that the collision probability $\operatorname{Pr}_{h \leftarrow H}\left[\mathrm{~h}(\mathrm{x})=\mathrm{h}\left(x^{\prime}\right)\right]$ should be at most $\frac{(1+\varepsilon)}{|Y|}$ on average with an infinitesimally small $\varepsilon$ since $\frac{2}{|Y|}$ is not good enough.

Definition 2. 10 Let $f(x)$ and $g(x)$ be two polynomials such that $f(x): A \rightarrow B$ and $g(x): B \rightarrow C$ where $A$, $B, C$ are arbitrary rings. Then the composition of $f(x)$ and $g(x)$ is well defined and given by $g(x) \circ f(x)=$ $(\mathrm{g} \circ \mathrm{f})(\mathrm{x})=\mathrm{g}(\mathrm{f}(\mathrm{x})) \quad \forall \mathrm{x} \in \mathrm{A}$.

Example 2.11 Let $\mathrm{f}(\mathrm{x})=3 \mathrm{x}+1$ and $\mathrm{g}(\mathrm{x})=\mathrm{x}-2$. Clearly, $(\mathrm{g} \circ \mathrm{f})(\mathrm{x})=3 \mathrm{x}-1$.
Definition 2.12 Consider two ciphers $\psi$ and $\varphi$. We define addition-composition homomorphic encryption by $\eta(\psi \oplus \varphi)=\eta(\psi) \circ \eta(\varphi)$ where $\circ$ is a composite function and $\oplus$ is an additive function.

Definition 2.13 Given two groups $G_{1}$ and $G_{2}$, we say $G_{1}$ is orthogonal to $G_{2}$ if $<G_{1}, G_{2}>=0$. We note that taking $\mathrm{G}_{1}^{s}=\hat{G}(\mathrm{C}) \lambda c$ where $\lambda c=\Theta_{i \in C} x_{i}$ we can consider the orthogonality aspect. First we consider Parsevals equality. $\sum_{c \leq[l]} \hat{G}(c)^{2}=\underset{x}{E}\left[G(x)^{2}\right]$

## 3. Results and Discussions

First we give some preliminaries before we move to the main results.
Lemma 3.1 For all $a \in Z_{l}, D_{l}\left(\mathrm{E}_{l}(a)\right)=a$ is true.
Proof: Let $\mathrm{y}=\mathrm{E}_{\mathrm{l}}(\mathrm{a})$ and b be the random number used for the message encryption. It is clear that b mod $\mathrm{n}=\mathrm{y}$ $\qquad$
Now, since 1 divides $n$ equation (1) implies that $y \bmod l=(b \bmod n) \bmod p=a$, for all prime numbers $p$.
Example 3.2: Let $\mathrm{l}=11, \mathrm{k}=7, \mathrm{n}=77=1 \bullet \mathrm{k}$ and $\mathrm{a}_{1}=5$ where $\mathrm{E}(5)=38$ and $\mathrm{a}_{2}=2$ where $\mathrm{E}(2)=13$ clearly $(38 x 13) \bmod 77=32$. When we decrypt 32 we obtain $10=32 \bmod 11$.

Lemma 3.2 For all $s, t \in Z_{l}, D(E(s) t)=D(E(s t))$
Proof : We first give $\mathrm{E}(\mathrm{s}) \mathrm{t}$ and $\mathrm{E}(\mathrm{st})$ a critical look since multiplication is defined pointwise. $\mathrm{E}(\mathrm{s}) \mathrm{t}$ : To do the encryption of $S$ we first choose $a_{1}$ such that $s \equiv a_{1} \bmod 1$ i.e. $a_{1}=\beta_{1} 1+$ s. Encrypting, we obtain $\mathrm{y}_{1} \equiv \mathrm{a}_{1} \bmod \mathrm{n}$ and hence $\mathrm{a}_{1}=\beta_{2} \mathrm{n}+\mathrm{y}_{1}$. Therefore $\beta_{1} \mathrm{l}+\mathrm{s}=\beta_{2} \mathrm{n}+\mathrm{y}_{1}$ and solving for $\mathrm{y}_{1}$ we obtain $\mathrm{y}_{1}=$ $\beta_{1} 1-\beta_{2} \mathrm{n}+\mathrm{s}=\left(\beta_{1}-\beta_{2} \mathrm{k}\right) 1+\mathrm{s}$

Now since $\mathrm{E}(\mathrm{s})=\mathrm{y}_{1}$ and $\mathrm{E}(\mathrm{s}) \mathrm{t}=\mathrm{y}_{1} \mathrm{t}$ we have $\mathrm{y}_{1} \mathrm{t}=\left(\mathrm{t} \beta_{1}-\mathrm{t} \beta_{2} \mathrm{k}\right) 1+\mathrm{ts}$ which when you decrypt you obtain $\mathrm{D}(\mathrm{E}(\mathrm{s}) \mathrm{t})=\mathrm{D}\left(\mathrm{y}_{1} \mathrm{t}\right)=\mathrm{y}_{1} \mathrm{tmod} \mathrm{l}=\mathrm{st}$
$\mathrm{E}(\mathrm{st})$ : To encrypt st we choose $\mathrm{a}_{2}$ such that $\mathrm{st}=\mathrm{a}_{2} \bmod 1$ where $\mathrm{a}_{2}=\beta_{2} 1+\mathrm{st}$. We then encrypt st as $\mathrm{y}_{2}=$ $\mathrm{a}_{2} \bmod \mathrm{n} \Rightarrow \mathrm{a}_{2}=\beta_{4} \mathrm{n}+\mathrm{y}_{2}$. Solving for $\mathrm{y}_{2}$ we obtain $\mathrm{y}_{2}=\left(\beta_{3}-\beta_{4} \mathrm{k}\right) 1+$ st which when decrypted yields $\mathrm{D}(\mathrm{E}(\mathrm{st}))=\mathrm{D}\left(\mathrm{y}_{2}\right) \mathrm{y}_{2} \bmod \mathrm{l}=\mathrm{st}$

Now $D(E(s t))=D(E(s) t)$ from Eqn. 4 and Eqn. 5. Hence $y_{1} t \bmod 1=s t=y_{2} \bmod p \Rightarrow D(E(s) t)=$ $\mathrm{D}(\mathrm{E}(\mathrm{s}) \mathrm{t})$ with modulus 1 . This completes the proof.

For computation of the main result we need the following concepts.

## Lemma 3.3

Take a real number x from the set $\mathrm{y}\left(\mathrm{k}_{1}, \ldots \ldots . ., \mathrm{k}_{\mathrm{m}}\right)$ then any ciphertext C from $\mathrm{C}\left(\mathrm{k}_{1}, \ldots \ldots . ., \mathrm{k}_{\mathrm{m}}\right)$ can be correctly decrypted by the algorithm $\mathrm{C}-[c x / l]$. For proof see (Craig, 2009).

At this point we need to discuss the Gentry Scheme and its implementation (Coron et al, 2011). For understanding $\lceil x\rceil$ means rounding up of $\mathrm{x},\lfloor x\rfloor$ means rounding down x and $[x]$ rounding x to the nearest integer.

Lemma 3.4 A family H of hash functions $\mathrm{h}: \mathrm{X} \rightarrow \mathrm{Y}$ is pairwise independent if for all $\mathrm{x} \neq \mathrm{x}$, it holds that $\operatorname{Pr}_{\mathrm{h}}\left[\mathrm{h}(\mathrm{x})=\mathrm{h}\left(\mathrm{x}^{\prime}\right)\right]=1 /|Y|$. Now it is obvious that $\mathrm{h}^{\prime}$ is not exactly pairwise independent therefore a general definition is necessary. For proof see (Coron, 2011), Lemma 6.

Theorem 3.5 Let H be a family of $\mathcal{E}$ - pairwise independent hash functions. Suppose that $\mathrm{h} \leftarrow \mathrm{H}$ and $\mathrm{x} \leftarrow X$ are chosen uniformly and independently. Then $(\mathrm{h}, \mathrm{h}(\mathrm{x}))$ is $\left(\frac{1}{2} \sqrt{|Y| /|X|+\varepsilon)}\right.$ - uniform over H x Y.

Proof: Let $\mathrm{p} \in \mathfrak{R}^{H x Y}$ denote the probability vector corresponding to a random choice of $\mathrm{x} \in X$ and $\mathrm{h} \in H$.
We must show that: $|p-1|_{1} \leq \sqrt{|H| \bullet|Y|} \cdot\|p-1\|_{2}=\sqrt{|H| \cdot|Y|} \sqrt{\left.\|p\| \frac{2}{2}-\| 1 \right\rvert\, \frac{2}{2}}$
We have $\|1\| \frac{2}{2}=1 /(|H| \cdot|Y|)$ and by Parseval's equality

$$
\begin{gathered}
\|p\| \frac{2}{2}=\sum_{\left(h^{\prime}, y\right) \in H X Y} \operatorname{Pr}_{(h, x) \leftarrow H x X}\left[h=h^{\prime} ; h(x)=y\right]^{2}=\frac{1}{|H|^{2}} \sum_{(h, y) \in H x Y} \operatorname{Pr}_{x \leftarrow X}[h(x)=y]^{2} \\
=\frac{1}{|H|^{2}} \sum_{(h, y) \in H x X}\left(\frac{1}{|X|^{2}} \sum_{\left(x, x^{\prime}\right) \in X^{2}} 1_{h(x)=y}\right)^{2}=\frac{1}{|H|^{2} \cdot|X|^{2}} \sum_{\left(x, x^{\prime}\right) \in X^{2}} \sum_{h \in H} 1_{h(x)=h\left(x^{\prime}\right)} \\
=\frac{1}{|H| \cdot|X|^{2}} \sum_{\left(x, x^{\prime}\right) \in X^{2}} \operatorname{Pr}_{h \leftarrow H}\left[h(x)=h\left(x^{\prime}\right)\right]=\frac{1}{|H| \cdot|X|}+\frac{1}{|H| \cdot|X|^{2}} \sum_{x \neq x^{\prime}} \operatorname{Pr}_{h \leftarrow H}\left[h(x)=h\left(x^{\prime}\right)\right] \leq \frac{1}{|H| \cdot|X|}+\frac{1+\varepsilon}{|H| \cdot|Y|}
\end{gathered}
$$

Hence, the statistical distance is bounded as:

$$
|p-1|_{1} \leq \sqrt{|H| \cdot|Y|} \sqrt{\frac{1}{|H| \cdot|X|}+\frac{1+\varepsilon}{|H| \cdot|Y|}-\frac{1}{|H| \cdot|Y|}=\sqrt{\frac{|Y|}{|X|}+\varepsilon}} \text { as desired. }
$$

Theorem 3.6 For an odd prime integer q , the hash function family H is $\varepsilon$-pairwise independent, with:

$$
\varepsilon=\frac{1}{q}+\frac{\beta^{2}}{2^{\alpha \beta^{2}-2(\alpha+1) \beta}} .
$$

Proof: For each choice of $\mathrm{b} \neq b^{\prime}$, the probability $\operatorname{Pr}_{h \leftarrow H}\left[h(b)=h\left(b^{\prime}\right)\right]$ can be expressed in terms of the number of zeros of a certain hyperbolic quadratic form in $\mathrm{Z}_{q}^{2 \beta}$. More precisely let $\mathrm{A}=\left(\mathrm{a}_{i j}\right)$ be the $\beta x \beta$ matrix in $\mathrm{M}_{\beta}\left(\mathrm{Z}_{q}\right)$ given by $\mathrm{a}_{i j}=b_{i j}-b_{i j}^{\prime}$. We have:

$$
\underset{h}{\operatorname{Pr}}\left[h(b)=h\left(b^{\prime}\right)\right]=\frac{1}{q^{2 \beta}} \#\left\{\left(u_{1}, \ldots \ldots ., u_{\beta}, v_{1}, \ldots \ldots, v_{\beta}\right) \in Z_{q}^{2 \beta}: \sum_{1 \leq i, j \leq \beta} a_{i j} u_{i} v_{j}=0\right\}
$$

Now the quadratic form $\mathrm{Q}=\sum_{1 \leq i, j \leq \beta} a_{i j} u_{i} v_{j}$ has the matrix $\frac{1}{2}\left(\begin{array}{cc}0 & A \\ A^{T} & 0\end{array}\right)$, which is clearly conjugate to $\frac{1}{2}\left(\begin{array}{ll}0 & J \\ J & 0\end{array}\right)$ where J is the canonical row echelon form of A. It follows that Q is the orthogonal sum of $r$ hyperbolic planes, with $r$ the rank of A. Hence, its number of zeros is well-known:

$$
\#\left\{\left(\mathrm{u}_{1}, \ldots \ldots, u_{\beta}, v_{1}, \ldots \ldots ., v_{\beta}\right) \in Z_{q}^{2 \beta}: \sum_{1 \leq i, j \leq \beta} a_{i j} u_{i} v_{j}=0\right\}=\mathrm{q}^{2 \beta-1}+q^{2 \beta-r}-q^{2 \beta-r-1}
$$

In particular, we get: $\operatorname{Pr}_{h}\left[h(b)=h\left(b^{\prime}\right)\right]-\frac{1}{q} \leq \frac{1}{q^{r}}$

This estimate is quite sufficient for our purposes, except in the case where $r=1$. Therefore, we need to bound the number of pairs $\left(b, b^{\prime}\right)$ such that the corresponding matrix $A$ is of rank 1 . Noting that $A$ has all its entries in $-2^{\alpha}+1, \ldots \ldots, 2^{\alpha}-1, \quad$ it is enough to bound the cardinality of the set $U_{\alpha}$ of matrices of rank 1 in $\mathbf{M}_{\beta}\left(Z_{q}\right)$ with entries in that interval. To do so, note that a matrix of rank 1 with a nonzero upper-left entry is entirely determined by its first line and its first column. If the entries are in $\{-$ $\left.2^{\alpha}+1, \ldots \ldots . . ., 2^{\alpha}-1\right\}$, this leaves $2^{\alpha+1}-2$ choices for the upper-left entries and $\left(2^{\alpha+1}-1\right)^{2 \beta-2}$ choices for the remainder of the first line and the first column. Hence, there are less than $2^{2(\alpha+1)(\beta-1)}$ matrices in $\mathrm{U}_{\alpha}$ with a nonzero upper-left entry (and usually much fewer, since not all first lines and first columns need to give rise to matrices with all their entries in the proper interval). The same argument can be applied to any other nonzero entry (i,j), leading to the coarse bound: $\left|U_{x}\right|<\beta^{2} .2^{2(\alpha+1) \beta}$ Now, the number of pairs (b,b') such that the corresponding matrix A is of rank 1 is at most $|X| .\left|U_{x}\right|$, since for any choice of b , there are at most $\left|U_{x}\right|$ possible values of b ' such that A is in $\mathrm{U}_{\alpha}$. We can thus bound the value $\delta$ defined by:

$$
\delta=\frac{|Y|}{|X|^{2}} \sum_{b \neq b^{\prime}}\left(\operatorname{Pr}\left[h(b)=h\left(b^{\prime}\right)\right]-\frac{1}{|Y|}\right)
$$

as required. Indeed:

$$
\begin{aligned}
& \delta=\frac{q}{|X|^{2}} \sum_{b \neq b^{\prime}}\left(\operatorname{Pr}\left[h(b)=h\left(b^{\prime}\right)\right]-\frac{1}{q}\right) \leq \frac{q}{|X|^{2}}\left(\sum_{\substack{b \neq b^{\prime} \\
A \notin U_{\alpha}}} \frac{1}{q^{2}}+\sum_{\substack{b \neq b^{\prime} \\
A \in U_{\alpha}}} \frac{1}{q}\right) \\
& \leq \frac{q}{|X|^{2}}\left(\frac{|X|^{2}}{q^{2}}+\frac{|X| \cdot\left|U_{\alpha}\right|}{q}\right) \leq \frac{1}{q}+\frac{\left|U_{\alpha}\right|}{|X|} \leq \frac{1}{q}+\frac{\beta^{2}}{2^{\alpha \beta^{2}-2(\alpha+1) \beta}}
\end{aligned}
$$

Theorem 3.7 Let K be a field and $\pi$ the principal ideal. Consider $\mathrm{p}, \alpha \in \pi$. Then $\mathrm{w}(\mathrm{x})=\delta(x) \circ \mathrm{v}(\mathrm{x})$ over K such that $\|\delta(x)\|_{\infty} \leq \sqrt{j_{k}(4 / 3)^{(3 k-1) / 4}{\beta_{k}}^{n / 2 k-1}}$, for all xin K and w , v and $\delta$ in $\pi$.

Proof: Since $\alpha$ is a root of $\mathrm{f}_{n}(\mathrm{x})=\mathrm{x}^{n}+1$ modulo p so $\mathrm{x}^{n}+1=(\mathrm{x}-\alpha) \circ \mathrm{g}(\mathrm{x}) \bmod \mathrm{p}$. Without loss of generality we assume that $\mathrm{g}(\mathrm{x})=\mathrm{x}^{n-1}+\mathrm{g}_{n-2} \mathrm{x}^{n-2}+\ldots \ldots . .+\mathrm{g}_{0}$. Hence, we obtain the following lattice $\left[\begin{array}{cccc}g_{0} & g_{1} & \cdot & 1 \\ -1 & g_{0} & \cdot & g_{n-2} \\ \cdot & \cdot & \cdot & \cdot \\ 0 & 0 & \cdot & p\end{array}\right]$

We need to reduce this lattice. To do this we invoke the lattice reduction algorithm and we obtain $w(x)$ $=\delta(x) \circ \mathrm{v}(\mathrm{x})$ such that equality (5) holds. Moreover $\mathrm{w}(\mathrm{x}) \in \mathfrak{R}$ since $\mathrm{u}(\mathrm{x}) \circ \mathrm{v}(\mathrm{x})=\mathrm{p}_{\bmod } \mathrm{f}_{n}(\mathrm{x})$.

Example 3.8 Let $n=4, u(x)=159+8 x+4 x^{2}+2 x^{3}=\left[\begin{array}{llll}159 & 8 & 4 & 2\end{array}\right], p=641407153, v(x)=4027071-204800 x-$ $91520 x^{2}-40898 x^{3} . u(x)$ and $f_{4}(x)=1+x^{4}$ are factored as follows:
$\left[\begin{array}{lll}159 & 8 & 4 \\ 2\end{array}\right]=2 *[[[269121861] 1][[918230811] 1]] \bmod 641407153$
$\left[\begin{array}{lllll}1 & 0 & 0 & 0 & 1\end{array}\right]=\left[\left[\left[\begin{array}{lll}26912186 & 1\end{array}\right] 1\right]\left[\left[\begin{array}{lll}91823081 & 1\end{array}\right] 1\right]\right] \bmod 641407153$
So, $\alpha=p-26912186=614494967$ and the public key is $p k=(p, \alpha)$. According to pk , one computes $\mathrm{g}(\mathrm{x})=[382839894343459750614494967$ 1]. To obtain $\mathrm{w}(\mathrm{x})$, one constructs lattice M and calls the LLL algorithm for M. In fact, one finds the exact solution $v(x)$ for this small example. Without loss of generality, assume $w(x)=\delta(x) v(x)=[489689338248934303943$ 15954106]. To be simplicity, we compute $a^{2} \bmod p=343459750$ and $a^{3} \bmod p=382839894$.

To find $[\delta(x)]_{2}$, one first computes a ciphertext

$$
\begin{aligned}
& c=a(x)(\alpha)=(2 r(x)+m(x)(\alpha) \bmod (p) \\
& =\left(3 * 382839894+4 * 343459750+5^{*} 614494967+9\right) \bmod (p) \\
& =463576302 \\
& d=\lfloor 463576302 / p x[4896893382489343039415954106+[0.50 .50 .50 .5\rfloor \\
& =[3539224-2764437311067011530812]
\end{aligned}
$$

Since $d \bmod 2=[\delta(x)]_{2} x[a(x)]_{2} \bmod 2,[\delta(x)]_{2}=d \bmod 2 x\left([a(x)]_{2}\right)^{-1} \bmod 2=\left[\begin{array}{llll}1 & 1 & 1 & 0\end{array}\right]$ Thus, one decrypts a ciphertext by using equivalent secret key $\mathrm{w}(\mathrm{x}),[\boldsymbol{\delta}(\mathrm{x})]_{2}$.

Let $\mathrm{R}=\mathrm{Z}[\mathrm{x}] / \phi(x)$ where $\phi(x)$ is irreducible over $\mathrm{Q}[\mathrm{x}]$ but factor modulo t . If $\phi$ splits exactly into r distinct irreducible factors of degree $\mathrm{g}=\mathrm{n} / \mathrm{r}=\varphi(d) / r$ i.e. $\phi(x)=\prod_{j=1}^{r} j_{j}(x)$. Then by Chinese Remainder Theorem, the following $\mathrm{R} t \cong \mathrm{Z}_{t}[\mathrm{x}] /\left(\mathrm{f}_{1}(\mathrm{x}) \otimes \ldots \ldots \otimes \mathrm{Z}_{t}[\mathrm{x}] / \mathrm{f}_{r}(\mathrm{x})\right) \quad$ is a natural isomorphism which is obtained. In particular this helps to add and multiply in parallel. In our new technique we obtain the addition-composition via tensor products as shown in the main results below.

Lemma 3.9 Generally, $\eta\left(\sum_{i=1}^{m} \chi_{i}\right):=\Theta \eta\left(\chi_{i}\right) \quad \forall m \in \mathrm{~N}=\mathrm{Z}^{+}$
Proof: Definition is well posed and defined. To see this consider $\boldsymbol{\theta}$ and $\tau$ and $\mathrm{z} \in \mathrm{Z}^{+}$where $\mathrm{z}=\mathrm{Z}$.
So $\quad \boldsymbol{\theta}=\lambda^{x} \circ \alpha_{1}^{y} \bmod n^{2}$

$$
\begin{aligned}
\tau & =\lambda^{k} \circ \alpha_{2}^{y} \bmod n^{2} \\
\theta \circ \tau & =\lambda^{x} \alpha_{1}^{y} \circ \lambda^{k} \alpha_{2} \operatorname{modn} \\
& =\lambda^{x+k} \circ\left(\alpha_{1} \alpha_{2}\right)^{y} \bmod \mathrm{n}^{2}
\end{aligned}
$$

So $\theta_{1} \circ \theta_{2} \circ$ $\qquad$ $\circ \theta_{m}=\lambda^{\left(x_{1}+x_{2}+\ldots \ldots .+x_{m}\right)} \circ\left(\left(\lambda_{1} \lambda_{2} \ldots \ldots . . . . . \lambda_{m}\right)^{y} \bmod n^{m}\right.$ and this completes proof.

Theorem 3.10 Let $\left(G_{1}, \ldots \ldots, G_{m}\right)$ be a homomorphic private key encryption scheme with respect to addition-composition homomorphism and a set of families of polynomial sized spaces (are private key encryption scheme, $\mathrm{H}_{i}$ is a probabilistic polynomial-time algorithm and exists a polynomial $\mathrm{m}(\circ)$ such that for every space $\left\{\mathrm{C}_{i}\right\} \mathrm{i} \in \mathrm{N}_{\in} \mathrm{C}, \mathrm{m} \in \mathrm{N}$ polynomial $((\circ))$, keys $\left(\mathrm{e}_{i}, \mathrm{~d}_{i}\right)$ and $\mathrm{l}=1(\mathrm{~m})$ single but messages $\mathrm{b}_{i}-\mathrm{b}_{l} \in\{0,1\}$ the following holds:
(i) Correct decryption of addition-composition homomorphically generates encryptions

$$
\mathrm{D}_{i}\left(\mathrm { H } _ { i } \left(\mathrm{C}_{l}, \mathrm{E}_{e}\left(\mathrm{~b}_{1}\right), \ldots \ldots \ldots \mathrm{E}_{e}\left(\mathrm{~b}_{l}\right)=\mathrm{C}_{l}\left(\mathrm{~b}_{1} \ldots . \mathrm{b}_{l}\right)(\mathrm{i}=1, \ldots \ldots \ldots, \mathrm{~m})\right.\right.
$$

(ii) The length of addition-composition homomorphically generated encryption is independent of 1 and is shorter i.e.

$$
\left|H_{i}\right| \mid C_{l} E_{e}\left(b_{1}, \ldots \ldots . . . E_{e}\left(b_{l}\right) \leq \mathrm{m}(\mathrm{n}) \quad \forall n \in V\right.
$$

Proof: By Lemma 3.9, addition-composition homomorphic encryption is well defined. So by Definition 2.10 it is easy to see that $\mathrm{D}\left(\mathrm{H}_{i}\right)$ depends in $\mathrm{f}_{i}(\mathrm{x})$ and invoking Theorem 3.7, and Lemma 3.9, exactness is obtained. Linearity is trivial and the proof is complete.

Theorem 3.11: Let $G_{1}, \ldots \ldots . . G_{m}$ be as a base in the theorem $X$ then for all $m_{\in} N, b \in\{0,1\}$ and $\left.\mathrm{C}\left(\mathrm{G}_{1} \circ \mathrm{G}_{2}\right), \mathrm{k}\right) \leftarrow \mathrm{G}^{\prime}\left(\mathrm{l}^{m}\right)$ then $\mathrm{D}_{k}^{l}\left(\mathrm{E}_{G_{1} \circ G_{2}}^{l}(b)\right)=\mathrm{b}$.

Proof: First consider the generation key $\mathrm{G}^{l}\left(l^{m}\right)$ and encryption $\mathrm{E}^{l}\left(\mathrm{G}_{1} \circ \mathrm{G}_{2}\right)$ and decryption $\mathrm{D}_{k}^{l}(\mathrm{c})$ : output $\mathrm{D}_{k}(\mathrm{c})$.

Next consider the first property of addition-composition encryption. If we consider Theorem 3.10, then analogously, $\mathrm{D}_{k}^{l}\left(\mathrm{E}_{G_{1} \circ G_{2}}^{l}(\mathrm{~b})\right)=\mathrm{D}_{k}\left(\mathrm{H} \oplus\left(\mathrm{G}_{1} \circ \mathrm{G}_{2}\right)=\underset{i=1}{\oplus} D_{k}\left(C_{i}\right)\right.$ where $\oplus$ denotes the addition modulo i $\mathrm{C}_{i}=G_{i} \mathrm{i}_{\in} \mathrm{C}$ and $\mathrm{C}_{i}=G_{i}$ otherwise. Since $\mathrm{D}_{i}$ decrypts correctly $\mathrm{D}_{k}\left(\mathrm{G}_{i}\right)=0$ otherwise $\mathrm{D}_{k}\left(\mathrm{G}_{i}\right)=1$, therefore, $\mathrm{D}_{k}^{l}\left(\mathrm{E}_{G_{1} \mathrm{O}_{2}}^{l}(\mathrm{~b})\right)=\oplus_{i \in C} 1=|\mathrm{C}| \bmod \mathrm{i}=\mathrm{b}$. The next step is to ensure that the scheme is semantically secure.

Theorem 3.12 If $\left(\mathrm{G}_{1}, \ldots, \mathrm{G}_{m}\right)$ is a semantically secure multiple message private key scheme then $\left(\mathrm{G}_{i}\right.$, $\left.\mathrm{E}_{i}^{\prime}, \mathrm{D}_{i}^{\prime}\right)$ is semantically secure public key scheme.

Proof: Assume without loss of generality that $\left(\mathrm{G}_{i}, \mathrm{E}_{i}, \mathrm{D}_{i}\right)$ is not semantically secure. Then it implies there exists a probabilistic polynomial time adversary $\mathrm{A}^{\prime}$ of a polynomial $\phi(\circ)$ such that for infinitely
many $\mathrm{n}_{\in} \mathrm{N} . \operatorname{Pr}_{\left(G_{1} \circ G_{2}\right), k \in G_{i}^{\prime}\left(l^{m}\right)}\left[\mathrm{A}^{\prime}\left(\mathrm{G}_{1}, \mathrm{G}_{2} \mathrm{E}_{G_{1} \circ G_{2}}^{\prime}(\mathrm{b})\right)=\mathrm{b}\right]<\frac{1}{i}+\frac{1}{p(m)} \quad \mathrm{b} \in R\{0,1\}$
The rest follows from Craig, (2009) analogously and this completes the proof.

## 4. Conclusions

The addition-multiplication homomorphic encryption is to the advantage of being usable in real time. The composite function element comes in handy since the result of the composite function $f(x)$ is encrypted and malicious hosts cannot know the results of the function. For instance in the mobile phone technology, the owner of the function gets the encrypted result through the function $g(x)$. For instance Richard Omollo is the owner of function $h(x)$ he wants to calculate the input c of Bernard

Okelo but he doesn't want to expose himself as the owner of the function. So he chooses $g(x)$ and creates $f(x)$ then sends it to Bernard Okelo. Bernard Okelo hence calculates the result through $f(x)$ using his input x and sends the result to Richard Omollo. Bernard Okelo cannot calculate $\mathrm{h}(\mathrm{x})$ because what he can see is just $f(x)$. Only Richard Omollo can get the real result of $h(x)$ through adding $f(x)$ into inverse function i.e. $h(x)=g^{-1}(f(x))$. For this particular reason, we have developed some theoretic results based on the addition-composition homomorphic encryption.
